NUCLEAR MEDICINE
MECKEL’S DIVERTICULUM SCAN

**OVERVIEW:** A nuclear medicine procedure is sometimes described as an “inside-out” x-ray, because it records radiation emitting from the patient’s body, rather than radiation that is directed through the patient’s body. Nuclear medicine procedures use small amounts of radioactive materials, called radiopharmaceuticals, to create images of anatomy. Radiopharmaceuticals are substances that are attracted to specific organs, bones or tissues. They are introduced into the patient’s body by injection, swallowing or inhalation. As the radiopharmaceutical travels through the body, it produces radioactive emissions. A special type of camera detects these emissions in the organ, bone or tissue being imaged and then records the information on a computer screen and on film.

**MECKEL’S DIVERTICULUM SCAN:** This exam is done to determine if areas of ectopic gastric mucosa are present in the bowel.

**PREP:** You will need to be NPO for 4 hours.

**PROCEDURE:** You will receive an IV injection of Tc-99m/04 and images of the abdomen taken. Imaging takes approximately 60 minutes.

**RESULTS:** These images will be reviewed by a radiologist and your ordering physician will contact you with the results in approximately 3 days. Your physician will advise you of the results and discuss what further procedures, if any, are needed.
